HEAT EXCHANGER FOR AN ELECTRONIC HEAT PUMP

TECHNICAL FIELD

5 This invention relates to electronic heat pumps and finned heat exchangers for transferring heat to and from such heat pumps.

For the sake of convenience, the invention will be described in relation to an electronic heat pump for a refrigeration system, but, it is to be understood that the invention is not limited thereto.

10 An electronic heat pump is defined herein as any heat pump or refrigerating module that directly depends upon flow of electrons and / or energy changes of electrons for its operation. This definition includes, but is not limited to, thermo-electric heat pumps and thermionic heat pumps.

BACKGROUND ART

15 The economic viability of a refrigeration system, which is based on the principles of a electronic heat pump, is primarily dependent on the efficiency of heat exchange between the electronic heat pump and two or more heat exchangers that collect and release the thermal load of refrigeration.

20 In a refrigeration system, heat can be dissipated effectively to the ambient air with the use of liquid coolants and radiators. However, the overall performance of a cooling system operating on an electronic heat pump is constrained by the heat transfer mechanism to the coolant fluid employed by the electronic heat pump.

25 In the prior art system disclosed in U.S. Patent No. 5,715,684, effective heat transfer is achieved by directing jets of liquid onto the face of the thermo-electric module.

According to one aspect of the invention there is provided a heat exchanger for an electronic heat pump comprising:

a thermally conductive base plate having first and second surfaces;
the first surface being flat and adapted to make intimate surface contact
5 with a surface of an electronic heat pump

the second surface being obverse to the first surface and supporting an array of thermally conductive fins, adjacent fins defining there between a plurality of channels.

In another prior art design, streams of coolant are forced to flow
10 along a series of channels over the face of the electronic heat pump - see U.S. Patent Nos. 5,653,111 and 5,822,993.

Both of these designs offer limitations in terms of heat transfer capacity where the area available for heat dissipation to coolant is restricted to the face area of the electronic heat pump. In addition, fluid
15 flow passages in Attey were made from non-conductive materials and no provision was made to incorporate additional heat flow paths to the coolant.

It is, therefore, an object of the present invention to extend the area of convective heat transfer between the electronic heat pump and coolant
20 to a size significantly greater than the available area on the surface of the electronic heat pump.

SUMMARY OF INVENTION

According to another aspect of the invention there is provided a heat
25 exchanger for one side of an electronic heat pump having a cold side and a hot side, said heat exchanger comprising:-

(i) a heat exchanger having a thermally conductive base plate adapted to be thermally coupled by one face to one side of the electronic heat pump and having a plurality of spaced apart thermally conductive heat exchanger fins projecting outwardly from the other face, adjacent fins defining channels there between, and

(ii) a manifold having a recess for receiving the finned base plate and the backing plate, a fluid inlet to the recess and a fluid outlet from the recess.

10 According to another aspect of the invention there is provided an electronic heat pump and heat exchanger system comprising:-

(i) an electronic heat pump having a hot side and a cold side,
(ii) a heat exchanger as defined above on at least one side of the electronic heat pump, and

15 (iii) means connecting the manifolds and adapted to provide a compressive sealing force between each base plate and the respective hot side and cold side of the electronic heat pump.

In one form of the invention, the thermally conductive base plate is integral with the fins.

20 The base plate of the heat exchanger may be joined to the face of the heat pump using soft solder with low melting point and good thermal conductivity such as Indium. Low melting point helps to carry out the process of fusing the base plate to the electronic heat pump with minimum thermal damage while, high thermal conductivity facilitates low thermal contact resistance at the joined interface.

25 A practical advantage of the invention is that, the geometrical arrangement of the heat exchanger enables the use of heat pump face area

in its entirety in the heat dissipation process to the fluid. In previous designs, participating heat transfer surfaces of the electronic heat pump were obstructed by mechanical components such as seals, which lead to unsatisfactory operation of the peripheral parts of the electronic heat pump.

5 One aspect of the present invention relates to the application of a finned heat exchanger in a device which utilises an electronic heat pump to generate a thermal gradient. A microchannel between a pair of adjacent fins is defined as a channel whose width is approximately 0.1 to 5mm and preferably about .4mm. In a preferred embodiment, the fins which define
10 the height of the microchannel are about 3.6mm high and having a thickness of about .8mm.

10 MODES FOR CARRYING OUT THE INVENTION

Referring to Figs. 1 and 2, the heat transfer system 10 according to this embodiment of the invention includes an electronic heat pump 11 having, in this instance, an upper cold side 12 and a lower hot side 13, a cold side finned heat exchanger 14 including a cold side backing plate 15
15 and a cold side manifold 16. On the hot side of the electronic heat pump 1 there is a hot side finned heat exchanger 17 including a hot side backing plate 18 and a hot side manifold 19.

The finned heat exchangers 14 and 17 each consist of a flat base plate 15 integral with or joined to a plurality of parallel equally spaced fins
20 21.

In order for the system to function, a liquid coolant is passed through the channels between the fins of the heat exchanger 17. Heat is then transferred away from the "hot side" of the thermoelectric module by conduction through the coolant in the heat exchanger channels and from
25 the surface of the heat exchanger, conduction through the heat exchanger 17 and through the solder or other jointing compound fixing the heat exchanger 17 to the adjacent surface of the thermoelectric module 11.

Heat is transferred through the thermoelectric module 11 in its normal manner. The second heat exchanger 14 may or may not be attached to the "cold side" of the thermoelectric module and operates in a similar fashion to the heat exchanger on the "hot side" but with the direction of heat flow reversed.

The respective orientation of the cold side and hot side are controlled by the electrical polarity of the electronic heat pump.

The dimensions of the system are based on the dimensions of the electronic heat pump 11, which is determined by its manufacturer.

In one configuration the heat exchanger 14, 17 consists of a flat base plate 15, 18 joined to a plurality of axially aligned, equally spaced fins, enclosed by a flat plate (e.g. 20) across the top of the fins. In another configuration the flat plate across the top of the fins is integral with the fins, forming channels surrounded by homogenous parent metal. The number of fins, the dimensions of the fins, the dimensions of the space between the fins are optimised by numerical analysis of flow and heat transfer to ensure the most efficient convection for a minimum of flow resistance. The cross-sectional shape of the fins may be further optimised from the simple rectangular shape to a more complex shape such as a trapezium to further heat transfer or to facilitate manufacture.

The surface of the base plate of the heat exchanger in contact with the heat pump is manufactured to sufficient flatness to ensure good thermal contact with the electronic heat pump. The heat exchanger is made of a material with high thermal conductivity, is mechanically robust and resistant to corrosive damage by the coolant.

Each manifold 16 and 19 has the following functions, (a) an enclosure to receive and discharge the coolant, via ports 100, from an

attached pipe, (b) a flow distributor to evenly distribute flow of coolant between the adjacent fins of the heat exchanger 14 or 17, (c) a structure to allow clamping forces between the heat exchangers and the electronic heat pump 11. To serve function (a) each manifold is fitted with an entry and exit port 100 for fluid, the entry and exit ports are located at opposite ends of a diagonal that is drawn across the rectangular cross section of the cover. The purpose of this orientation is to ensure even distribution of flow to the fins, according to an earlier established principle as discussed in U.S. Patent No. 5,653,111.

Adjacent to the exit and entry ports, there is a cavity 101 running from the port to at least the furthest fin. The purpose of the cavity 101 is to ensure an even distribution of flow from the port to the fins of the heat exchanger 14 and 17. Each manifold may be fitted with an equally spaced series of bolt-holes 102 running around the periphery of the cover. This allows provision of bolts and nuts to impose the said clamping force.

As shown in Fig. 2, the electronic heat pump 11 is sandwiched between the two heat exchangers. In the instance of a Peltier cell, the ceramic exterior faces 110, 111 are in close contact with the base plates 15, 18 of the heat exchangers. The base plates 15, 18 are restrained by their side edges soldered to a metallized surface on the ceramic faces 110, 111 and may be sealed against the interior surface 112 of the manifolds 16, 19. O-ring seals 113 may be used to prevent leakage of fluid from the channels 101 into the central area 114 containing the heat pump 1. As further illustrated in Fig. 2, the ports 100 lead into channels 101 which extend at least the full length of the array of fins 21. The distal edges of the fins or alternatively, the plate or surface 20 which encloses them is in contact with the interior surface of the manifold 16, 19.

Fig. 2 illustrates two distinct styles of heat exchanger fabrication. The upper or cold side heat exchanger comprises an array of fins 21 and the base plate 15. In this example, the array of fins and channels 21 include a covering plate 20 which may be integral with the fins or soldered onto the array of fins.

5 It is this covering plate 20 which is in contact with and sealed against the manifold 16 so that fluid flow between the channels 101 occurs only through the array of fins 21. Where manufacturing tolerances can be controlled, and as shown in the lower half of Fig. 2, the array of fins 21 may be open ended, with the distal tips of the fins contacting and sealing against the floor of the manifold
10 19. A third variation is depicted in Fig. 3.

Fig. 3 illustrates a resilient polymeric sheet 120 interposed between one or both heat exchangers and their respective manifolds 16, 19. These polymeric or soft metal sheets 120 may be used to ensure a proper resilient seal between an array of fins and its manifold when the manifolds are joined
15 together. In effect, the sheets 120 are capable of taking up manufacturing tolerances, or in the case where open ended fins are used (as shown in Fig. 3) actually serve to seal the channels between fins against the inner surface of the manifold.

The efficiency of a heat pump such as a thermoelectric device is
20 critically dependent on the temperature difference between the hot side and the cold side. Fig. 4 shows a graph of COP (coefficient of performance) vs ΔT for a typical thermoelectric module (Frost 76S from Kryotherm).

Figs. 5 and 6 show a series and a parallel arrangement of heat exchanger 'units' to obtain a larger refrigerating power than can be
25 achieved with a single heat exchanger and enclosed electronic heat pump. Fig. 5 illustrates a series arrangement of devices 10 of the type depicted in Fig. 1. It would be appreciated that by fluidly connecting adjacent devices

10 in a counter-current arrangement can result in the ability to accommodate greater thermal loads for a given rate of fluid flow. In this example, the hot side of the device 10 is connected to the hot side of an adjacent device, the flows of hot and cold liquids travelling in opposite
5 directions as illustrated. Fig. 6 illustrates the parallel connection of two pairs of devices 10, each pair operating in series. Again, the flows of hot and cold liquids are travelling in opposite directions to maximise thermal efficiency. The hot side fluid flows 130 are depicted as a solid line while the cold side fluid flows are illustrated with a dash line 131.

10 Fig. 7 illustrates a schematic system diagram illustrating an application of the device 10 of the present invention. In this example, a cold side heat secondary exchanger 150 is located within a refrigerated space 151. A small fan 152 circulates the air within the refrigerated space in an attempt to achieve thermal equilibrium. The cold side secondary heat
15 exchanger 150 is supplied with cold fluid from the electronic heat pump 10 by a pump 153. The output of the electronic heat pump's hot side manifold is delivered to a secondary hot side fan assisted heat exchanger 154, circulation between the secondary heat exchanger 154 and the heat pump 10 being accomplished by a second pump 155.

20 Fig. 8 illustrates an array of fins 161 which may be used in place of the rectangular fins depicted in, for example, Figs 1 and 3. These fins 161 are tapered and include longitudinal grooves 162 which serve to increase the surface area interface between the fins 161 and the channels 160. In this example, the side surfaces of each fin are provided with a pair of "V"
25 shaped grooves which promote heat transfer between the fin 161 and the channel 160. The same effect may be achieved by other forms of convolution of the fins surface or by roughening the surface of the fin.

Fig. 9 illustrates an alternate embodiment of an array of fins wherein the individual fins are replaced by a corrugated metal sheet 170 which is interposed between a pair of parallel sheets or plates 171, 172.

As shown in Fig. 10, two or more electronic heat pumps 11 may be stacked into a single working module 180. In this example, the cold sides 12 of a pair of heat exchangers 11 are arranged in a facing relationship and separated by a single finned heat exchanger 181. Each hot side 13 of the pair of electronic heat exchangers is associated with its own manifold and heat exchanger 182.

As shown in Fig. 11, liquid enters the upper and lower manifold entry ports 190 and exits through the hot side ports of the upper and lower manifolds 191. The central manifold and heat exchanger 192 circulates fluid past the cold sides of both of the heat pumps within the module 180.

Fig. 12 illustrates an array of fins 200. Each fin 201 is generally rectangular in cross section. Each pair of adjacent fins defines a microchannel there between. As shown in Fig. 13, the ends 202 of each fin 201 may be provided with a step 203 for the purpose of facilitating attachment to the manifold.

Fig. 14 illustrates the type of fin array which is required for the central manifold 181 depicted in Figs. 10 and 11. As shown in Fig. 15, the array comprises a central web 204 which has similarly configured fins 205 directed outwardly from both its upper and lower surfaces.

The efficiency of the heat pump will be enhanced significantly if the same amount of heat can be pumped from the hot or cold side at a lower temperature difference between the surface of the thermoelectric module and the liquid passing through the heat exchanger. Since heat flow is equal to $h_c \times \text{Area} \times \Delta T$ (where h_c is the heat transfer coefficient), a relatively

simple way to reduce ΔT is to increase Area. The design of the heat exchanger with multiple fins achieves this aim and leads directly to greater heat pump efficiency.

Further, however, there are several other important benefits that the narrow microchannels design confers. It has been found through recent research into the cooling of high heat load computer chips that the usage of microchannels leads to unexpectedly high heat transfer coefficients. The reasons are not yet clear but are believed to include the increased impact of surface tension and electric potential effects which lead to earlier transitions from laminar to turbulent flow. The effects of natural surface roughness are also magnified in microchannel flow and can contribute to the high heat transfer coefficients.

When applied to cooling computer chips, very high heat loads are encountered. Heat fluxes of 75 W/cm^2 are now being achieved. Relatively high ΔT 's are required for these heat loads which is in contrast with thermoelectrics. The heat exchanger design exploits the high heat transfer coefficients possible with microchannels and applies the benefit to achieve relatively low heat fluxes (less than 1 W/cm^2) at very low ΔT 's. These conditions are ideal for thermoelectric heat pumps and lead to significantly enhanced efficiencies.

Heat transfer in laminar flow is by conduction rather than by convection as is the case in turbulent flow. Because most liquids, including water, have low thermal conductivities this means that heat transfer coefficients are relatively low. The flow in the heat exchangers of this design is in the laminar region and particular attention must then be paid to heat transfer coefficients because of the deleterious effects of high temperature differentials on the thermoelectric module.

A benefit which is exploited in the design is the known feature that the h_c in developing laminar flow is significantly higher than in fully developed laminar flow. The length of channels is controlled to a significant degree by the physical size of the thermoelectric module, typically 40 mm square, and the dimensions of the channels have been optimised within these restrictions so that flow exists predominantly in the developing region.

It is possible to increase the rate of convective heat transfer, without using a finned heat exchanger, by increasing the flow speed of the coolant over the exterior of the electronic heat pump when the flow is in the turbulent region. The heat transfer coefficient is approximately proportional to flow rate when this occurs.

However, and as shown in Fig. 16, when the flow is laminar, according to the Nusselt equation from the theory of heat transfer in laminar flow, the heat transfer coefficient is related to flow velocity to only the power of 0.3. In other words, increasing flow speed has very little beneficial effect on the heat transfer coefficient. In laminar flow pump power is proportional to the square of the flow rate and therefore if this strategy is adopted it will have a negative impact on overall system efficiency, i.e. the total electric power (including thermoelectric module, pumps and fans) required to pump a given amount of heat will rise.

The adoption of a finned heat exchanger with its increased surface area and improved heat transfer coefficients due to the effect of the microchannels enables more efficient optimisation of the ancillary power consumption of the pumps and fans.

Heat flux from the walls of the channel into the liquid coolant is optimised when all parts of the channel surface are at a uniform

temperature. The design of the heat exchanger is such that this is achieved through careful consideration of fin height as well as spacing. The length of the fin is critical because thermal resistance is proportional to fin length. The narrow width of the channel eliminates the situation where the bulk of the fluid passes straight through a heat exchanger with the heat transfer restricted to a relatively thin film of fluid at the surface.

Fig. 17 shows temperature contours within a micro channel of one embodiment of a finned conductive heat exchanger having an aspect (i.e. width to height) ratio of 1:3.5 on the hot side of a heat pump, the heat flux being 40,000 W/m², inlet fluid temperature 27°C, flow rate 1 l/min with pure water coolant. These temperature gradients show minor variation (2.4°C) across the fluid, indicating that all of the fluid is involved in the heat transfer process with little bypass.

Fig. 18 shows temperature contours within a channel of a finned insulating heat exchanger having an aspect ratio of 1:3.4 on the hot side of a heat pump, the heat flux being 40,000 W/m², inlet fluid temperature 27°C, flow rate 1 l/min with pure water coolant.

The critical feature of the temperature profile is the difference in temperature between the fluid close to the heated surface and the bulk of the fluid. It can be seen that this difference is significantly less for the heat exchanger shown in Fig. 17 than for the earlier design involving plastic fins or partitions shown in Fig. 18 which has a temperature gradient of 30.7°C. This indicates that the heat exchanger has largely solved the problem of the earlier design where the bulk of the coolant remained effectively unheated during its passage through the heat exchanger.

The heat dissipation capability of the narrow channel heat exchanger is primarily dependent on the conduction of heat along the walls of the

channel and the convective heat transfer in the fluid at the channel walls. The combination of these two aspects determine the overall thermal resistance of the heat transfer process within the heat exchanger. Increased channel wall thickness and enhanced convective mechanism
5 resulting from higher fluid velocities act favourably to reduce the overall thermal resistance in the heat exchanger.

Using a computational heat and fluid flow model, the heat transfer performance of the narrow channel heat exchanger is evaluated and optimised to obtain the most effective flow arrangement. For a given fluid
10 mass flow rate and a fixed external heat flux applied to the top surface of the channel, the variation of fluid temperature contours with channel aspect ratio is illustrated in Figs. 19 to 24.

It is evident that, as the channel aspect ratio increases (narrow channel), heat tends to penetrate deeper into the fluid passage reducing the
15 difference between the highest and the lowest temperatures indicated in the fluid. Consequently, the fluid temperature distribution becomes more uniform in these channels. Thus, the narrow channels tend to exhibit a lower thermal resistance (or a higher thermal conductance) for heat flow to the fluid than the equivalent channels of small aspect ratios. The
20 mechanisms of convective heat transfer enhancement in narrow channels and the extended area available for heat dissipation are the primary factors that contribute to this behaviour. High thermal conductivity of channel wall also effectively helps to achieve further improvements in heat transfer performance.

25 While the heat transfer capability improves with the increased aspect ratio, higher fluid pumping power requirements in narrow channels determine the upper limit of the useable range of aspect ratio for these

channels. The range of aspect ratios found to be useful range from 4:1 to 15:1. When applied to a typical thermoelectric module which has surface dimensions of 40mm x 40mm the number of channels may range from a minimum of 10 up to a maximum of 100.

- 5 A thermally conductive base plate is integrated with the fins to ensure minimal thermal resistance to heat flow. This base plate could act as the wall of an electronic heat pump, replacing the low conductivity ceramic presently used.

- Careful control of thermal contact resistance between heat
10 exchanger base plate and electronic heat pump is critical to achieving high thermodynamic efficiency of the system. The extremely low thermal conductivity of air (approximately 0.03 W/m*K) causes a high thermal impedance to be generated by any gap exceeding approximately 5 micrometres thickness. Consequently, both contacting surfaces of the
15 heat pump and the heat exchanger must be flat to within approximately 1 micrometres tolerance to ensure a satisfactorily small contact gap. In low-cost manufacturing, such a small tolerance may be difficult to achieve so a solder joint may become necessary. The solder should have the highest practical level of thermal conductivity and a low melting point to facilitate
20 the joining of the heat exchanger to the surface of the electronic heat pump, without damage to the latter.

- The overall size of the heat exchanger is not limited to the surface area of the electronic heat pump. It can be made larger and because it is of high conductivity metal there will be minimal thermal resistance to the flow
25 of heat. This enables an even greater expansion of the surface area for heat exchange to a liquid coolant through channels.

Other high conductivity devices, such as heat pipes, can be used in conjunction with the heat exchanger in order to enlarge the potential contact area or to transport the heat load to a more convenient location for mounting of the heat exchanger.

5 In order to appreciate the enhanced mechanism of heat transfer provided by the invention for high heat flux thermoelectric cooling applications, it is appropriate to review the development of heat transfer techniques.

10 In cooling of electronic equipment, traditional heat transfer mechanisms such as natural convection, forced convection and boiling have been effectively applied and tested. In the past decade, requirement for operating heat flux levels of these devices has been steadily increasing from around 50 W/cm² to 100 W/cm². Even with various enhancement methods, conventional heat transfer equipment is inadequate for most of these applications owing to their poor thermal characteristics and large physical size. The quest for
15 miniaturisation in modern devices has created an urgent need for development of high heat flux modules and improved understanding of heat transfer phenomena.

20 The prior art includes many heat transfer mechanisms that generally yield significantly high levels of heat fluxes. Some such flow arrangements with inherently high rates of heat transfer are jet impingement cooling, interrupted jet cooling and heat transfer in very narrow passages or microchannels.

25 In jet cooling techniques, the thermal and hydrodynamic boundary layers associated with the flow are continuously changed causing a reduction in thermal resistance at the liquid-wall interface. Hence, the heat dissipation to the fluid is improved. However, due to high jet flow velocity requirements and wetting of surfaces, applications are limited to specific cases of heat transfer

situations. In a microchannel heat exchanger, a cooling liquid is forced through narrow channels (width of the order of 0.05 to 5mm) built in a plate attached to an electronic device to carry away the heat generated during its operation.

Through experimental methods, it has been established that, the heat transfer coefficients in microchannel flow tends to be about 60 times higher than those of conventional macroscale flow passages. Microchannel heat transfer is considered to have great potential for providing high rates of cooling necessary for modern instruments with high powered circuitry in applications such as Micro-Electric-Mechanical-Systems, high-speed computers, biomedical diagnostic probes, lasers and precision manufacturing.

Various studies indicate that the microchannel flow and heat transfer phenomena cannot be explained by conventional theories of transport mechanisms. for instance, the transition from laminar flow to turbulent flow starts much earlier (e.g., from $Re = 300$); the correlations between the friction factor and the Reynold number for microchannel flow are very different from that in classical theory of fluid mechanics; the apparent viscosity and the friction factor of a liquid flowing through a microchannel may be several times higher than that in the conventional theories. These special characteristics of flows and heat transfer in microchannels are the results of micron-scale channel size and, the interfacial electrokinetic and surface roughness effects near the solid-liquid interface. High convective heat flux rates achievable in microchannel flow is attributed to these vastly different flow phenomena that occur in narrow passages.

High rate of heat flux encountered in microchannels allow a compact microchannel heat sink system to have lower thermal resistance and to work under high cooling load situations. The microchannel heat sink technology is therefore increasingly being used in modern electronic packaging, high-speed

computers and other related industries. the heat exchanger design of the thermo-electric cooling module attempts to harness possible heat transfer enhancement in flow through narrow passages.

5 The preferred heat exchange is made of metal of high thermal conductivity and has several narrow rectangular passages through which the cooling liquid flows. High thermal conductivity helps to spread heat flux evenly around the channel walls that are in contact with the liquid, thereby increasing the effective area heat transfer to the fluid. Due to special flow characteristics in narrow passages as in microchannels, high heat transfer rates are present in
10 the flow. The developing nature of the flow through the passage further contributes to the heat transfer augmentation. The combined effect of all these mechanisms gives rise to significantly low thermal resistance between the thermo-electric module attached to the heat exchanger and the cooling fluid than previous designs of heat exchangers for similar applications.

CLAIMS

1. A heat exchanger for an electronic heat pump comprising:
a thermally conductive base plate having first and second surfaces;
the first surface being flat and adapted to make intimate surface contact
5 with a surface of an electronic heat pump
the second surface being obverse to the first surface and supporting an
array of thermally conductive fins, adjacent fins defining there between a
plurality of channels.
- 10 2. The heat exchanger of claim 1, wherein:
the flat plate resides within a manifold and serves as a thermally
conductive fluid barrier between a fluid passageway within the manifold; and
an electronic heat pump located against the first surface.
- 15 3. The heat exchanger of either of claims 1 or 2, wherein:
the array of fins is integral with the base plate.
4. The heat exchanger of any one of claims 1 - 3 , wherein:
the array of fins comprises an array of rectangular fins which further
20 comprises a covering plate;
the fins extending between the base plate and the covering plate;
the fins being integral with or soldered to the covering plate.
5. The heat exchanger of any one of claims 2 - 4, wherein:
25 the manifold comprises a fluid input port fluidly connected to a fluid input
channel and a fluid output port fluidly connected to a fluid output channel;

the fluid input and output channels being parallel and defining there between a location for situating the array of fins.

6. The heat exchanger of claim 5, wherein:

5 the input and output channels are located at either end of a central cavity within which the base plate may be located;
the base plate being in a sealing relationship with the cavity.

10 7. A heat exchanger module comprising a heat exchanger of the type described in any one of claims 1 - 6, in combination with another heat exchanger of the type described in any one of claims 1 - 6, assembled in a facing and sealed relationship and defining a gap between the base plates of each, an electronic heat pump residing in the gap and contacting both base plates.

15

8. A heat exchanger according to any one of claims 1 - 7, wherein:
a polymeric or soft metal sheet is interposed between an array of fins and a manifold.

20 9. The heat exchanger of any one of claims 1 - 8, wherein:
adjacent fins in an array define there between a plurality of microchannels.

10. A heat exchanger for one side of an electronic heat pump having a
25 cold side and a hot side, said heat exchanger comprising:-
a heat exchanger having a thermally conductive base plate adapted to be thermally coupled by one face to one side of the electronic heat pump

and having a plurality of spaced apart thermally conductive heat exchanger fins projecting outwardly from the other face, adjacent fins defining channels there between and

5 a manifold having a recess for receiving the finned base plate and the backing plate, a fluid inlet to the recess and a fluid outlet from the recess.

11. An electronic heat pump and heat exchanger system comprising:-
an electronic heat pump having a hot side and a cold side,
a heat exchanger as defined above on at least one side of the
10 electronic heat pump, and
means connecting the manifolds and adapted to provide a
compressive sealing force between each base plate and the respective hot
side and cold side of the electronic heat pump.
